1.0 INTRODUCTION.

The Sweep Module interfaces the low level logic signals from the Processor PCA to the CRT. It generates all drive signals and specialized voltages required by the CRT display.

2.0 OPERATING PARAMETERS.

A summary of operating parameters for the Sweep Module is contained in tables 1.0 through 4.0

Table 1.0 Physical Parameters

Part Number	Nomenclature	Size (L x W x D) +/-0.100 Inches	Weight (Pounds)
02620-60002	Sweep PCA	11.5 x 6.8 x 2	1

Table 2.0 Reliability and Environmental Information

- 3.0 FUNCTIONAL DESCRIPTION. Refer to the block diagram (figure 1), schematic diagram (figure 2), timing diagram (figure 3), the component location diagram (figure 4), and parts list (02620-60002) located in the appendix.

The Sweep Module consists of video, vertical and horizontal drive circuits. The Sweep module generates all of its special voltages within the horizontal section, and requires only +12 volts and +5 volts as input power.

3.1 VIDEO DRIVE.

- 3.1.1 The function of the video drive circuit is to interface the low level logic input signals from the processor PCA to the higher levels required to drive the CRT. The video circuitry must be very fast, and features rise and fall times of typically less than 10 nanoseconds.

- 3.1.2 Switching transistors Q4 and Q5 are open-collector buffers, while transistor Q6 acts as an active pull-up to +30 volts. Transistor Q4 with diodes CR13 and CR15 sets the half-bright level (+6 volts on the CRT cathode), while Q5 sets the full-bright level (0 volts on the CRT cathode). Blanked raster is obtained when both Q4 and Q5 are turned off, allowing Q6 to bias the CRT cathode at +30 volts. Neon bulb DS2 protects the video section during a CRT flashover.

3.2 VERTICAL DRIVE.

- 3.2.1 The vertical drive circuit generates the vertical scanning waveform which causes the electron beam in the CRT to be moved from the top to the bottom of the screen. Its input is a TTL vertical drive signal which goes low during vertical retrace.

- 3.2.2 Operational amplifier U3 is a Norton (current differencing) input op-amp. The vertical ramp is generated by U3-A. The ramp starts at 0 volts and integrates positive at a rate determined by U3-B and R1 (the height control). Reset occurs when the output of U2 goes high allowing the current through R6 to reset the integrator.

- 3.2.2.1 U3-B is another integrator which samples the vertical ramp and integrates it into a parabola which is used to slow the deflection down at the extremes of the ramp to correct for non-linearity due to the flatness of the CRT screen.

- 3.2.2.2 The output amplifier converts the voltage ramp from the integrators to a current which is applied to the deflection yoke. U3-C samples the current through the yoke (taken as a voltage across R23) and compares it to the ramp voltage. The yoke is AC coupled through C12 and C22. The DC operating point of the amplifier is stabilized by R21 and R22. Q1, C11, and CR14 form a boost circuit which raises the power supply voltage on the amplifier to 22 volts during vertical retrace.
- 3.3 HORIZONTAL DRIVE.
- 3.3.1 The Horizontal drive circuit generates the horizontal scan which sweeps the beam from left to right on the face of the CRT, and also the special voltages including the anode voltage (+12 KV) of the CRT.
- 3.3.2 The TTL Horizontal Drive signal is applied to one shot U1 which allows an adjustable delay that is used to center the raster by delaying horizontal reset with respect to video blanking.
- 3.3.2.1 The delayed Horizontal Drive signal is applied to transistor Q7 which drives the horizontal output transistor Q8 through T1. T1 is a regenerative transformer which samples the collector current of Q8 and adjusts its base current to "force" a beta of five. Q7 stops this action during horizontal retrace by overcoming the feedback action of T1 and keeping Q8 turned off with current supplied by R14 and C6.
- 3.3.2.2 The components associated with Q8 and the flyback transformer primary form a "ringing" horizontal sweep circuit. The flyback primary is connected so that +40 volts is generated and appears as a virtual input voltage due to the diode connected in series with the +12 volt actual input. The damper diode CR8 is two turns away from Q8 on the flyback transformer to improve linearity. C26 corrects non linearity due to the flatness of the CRT faceplate by slowing down the beam deflection at the sides.
- 3.3.2.3 In addition to +40 volts, the flyback supplies -40 volts, +800 volts, and +12 KV for CRT biasing. The +12 KV output is rectified inside the transformer, but the other supplies are rectified and filtered externally.
